Implement a class with the following declaration:

```
class polycoef {
private:
    INTEGER      deg;           //degree of polynomial
    REAL*        pc;           //array of len=deg+1 containing coefficients
    INTEGER      len;          //indexing is pc[i], i=0,...,deg
public:
    polycoef();                //default constructor
    polycoef(INTEGER degree);   //explicit constructor
    polycoef(const polycoef& a); //copy constructor
    ~polycoef();                //destructor
    polycoef& operator=(const polycoef& a); //assignment operator
    REAL& operator[] (INTEGER i); //lvalue element access
    const REAL& operator[] (INTEGER i) const; //rvalue element access
    INTEGER      degree() const; //returns deg
    friend polycoef operator+(const polycoef& a, const polycoef& b); //summation
};
```

The purpose of the class is to represent a polynomial and implement addition of polynomials.  
Here is a main that uses every method in the class

```
int main()
{
    polycoef a(3);
    for (INTEGER i=0; i<=a.degree(); i++) a[i] = REAL(i);
}
```

```

polycoef b(5);
for (INTEGER i=0; i<=b.degree(); i++) b[i] = REAL(i);
polycoef c;
c = a + b;
polycoef d = c;
for (INTEGER i=0; i<=c.degree(); i++) cout << c[i] <<" " << d[i] << '\n';
return 0;
}

```

This is a container class similar to `class intvec`. You can look at that code for hints on how to implement `class polycoef`. Notice that, unlike `class intvec`, the arguments of `operator+` need not have the same length; the `polycoef` that is returned will have length the larger of the two arguments.

If you are ambitious implement `operator*` for extra credit.

Turn in your code, a sample main that executes it, and the output.
